Flexcrypt is a small software application that will enable encryption and decryption of your emails and MSN. The reason for encrypting is to ensure the integrity and privacy of your email. Flexcrypt is very easy to install and use. After installation, simply add the email addresses you wish to send and receive encrypted emails with. For each address, you must make up a password. This password is the key used in order to decrypt the message, thus, you must inform the receiver of the encrypted email of your chosen password. Do this by phone or in person, NOT by un-encrypted email. This only has to be done once, after that, Flexcrypt will remember your password and encrypt/decrypt your messages automatically or as you choose. Flexcrypt gives you endpoint to endpoint security, this means that your email is encrypted at the moment it leaves your computer, and remains encrypted until it reaches the receiving persons computer. Flexcrypt Version 1.1 Change Log: · Fixed logging bug · Fixed bug in the way you can encrypt/decrypt all your accounts at the same time. · Fixed bug in the part that calculates how long the time between decryption/encryption should be. · Fixed bug with the server for sending encrypted messages. · Refined the interface a bit. · Miscellaneous bug fixes · Improved the documentation and interface. · Documentation added. · FAQ updated. · Added some new features like the possibility of encrypting all your accounts at the same time. · Fixed a bug in the part that tells you when to update the key. · Added server for sending encrypted emails. · Improved all the menus. · Various bug fixes · The developers want to thank Mark Garlick from looblabs for the help in programming. · The developers want to thank Colin J. for testing Flexcrypt and for the useful feedback. · The developers want to thank all the users for their help in testing Flexcrypt. Plain and simple. The answer is YES. I searched on the internet to find out the answer to this question. There are a lot of opinions on the Internet, and some of them say that there is NO encryption on the internet, while others say that there is NO encryption without a certificate. The best answers I found were in a forum I read: cc6f4944dd

MACRO not defined means that the debugger's memory is out of space. When this error occurs, the output buffer is filled with characters and the previous breakpoint fails to restart. If you receive 'Program Aborted' or 'Access Violation' debugging errors it may be caused by a bug in the program you are debugging or by a setting in your project settings. As the first step in debugging, ensure you're using the most current version of Visual Studio (i.e. Visual Studio 2010). If not, get it downloaded from the Visual Studio website. KEYMACRO Description: Reset to default means that the debugger has been reset to its default settings for the current thread. This error is raised when a debugger is not attached or when an exception is generated and the debugger has been forced to stop. If you're receiving 'Invalid Window' errors, it may be caused by a bug in the program you're debugging or by a setting in your project settings. As the first step in debugging, ensure you're using the most current version of Visual Studio (i.e. Visual Studio 2010). If not, get it downloaded from the Visual Studio website. KEYMACRO Description: Jobs can be launched from the Debugging tab of the Options dialog (Tools->Options->Debugging). A job is a single piece of code which is executed by the debugger. A job can be any executable, a source file, an entire module or library and can be set to pause or continue execution, to break into execution when a condition is true, or to stop execution when a condition is false. A job can be terminated manually, automatically when the program exits, or automatically when a condition is fulfilled. A task is a job which can be scheduled to run at a specific time. If you are not using the 64-bit version of Visual Studio, the debugging tools may be restricted to a 32-bit process. If you're debugging with a debugger, you can change the process to be 64-bit by changing the platform target to the 'x64' platform in the Project Properties->Configuration Properties->General->Active Solution Platform menu item. KEYMACRO Description: It's very likely your program is exiting abnormally due to an error that's happening on the Windows side. Possible causes for this error include an incompatible version of Windows, an incompatible version of the CLR or a broken installation of the debugger. The 'HRESULT Unknown' error is
