Activity of some quinoline derivatives against *Psoroptes cuniculi*. The in vitro activity of some quinoline derivatives, including quinacrine, mebendazole, dimetridazole and fenbendazole against *Psoroptes cuniculi* was evaluated by in vitro tests using the high and low prion strains. The most active compound against both strains was fenbendazole (MIC = 0.015 mg/mL). Moreover, the activity of both quinoline derivatives against *Sporothrix schenckii* and *Trichophyton mentagrophytes* var. *interdigitale* was also tested. Two fundamental processes underlie patterning in the nervous system. First, neural precursor cells in many regions of the brain generate positional cues required for neural specification. Second, the final identities of the derived neurons are determined by the pattern of cell type-specific transcriptional regulatory proteins. Work over the past few years has begun to uncover how positional cues are produced in the nascent brain and how identity is specified in neural progenitor cells. Molecular mechanisms that specify and direct the embryonic or adult neural cell fate appear to be divergent in most cases. The growth cone of an axon, on the other hand, often contains the machinery for the generation and patterning of axon tracts. Recent work has shown that the growth cone can autonomously determine its trajectory and that many of the components required for growth cone outgrowth and guidance are conserved between invertebrates and vertebrates. In addition, work from our laboratory suggests that the growth cones of axons in the developing chick optic nerve follow a stereotypic growth pattern. Based on these observations, it is hypothesized that axon growth cones can act as coordinators of gene activity that specify their axonal path. To test this hypothesis, a gene-based approach will be used to examine the growth cones of developing chick optic nerve axons. The goal of this proposal is to use an in vivo gene-based approach to study how axon guidance receptors, cell adhesion molecules, and signaling proteins direct axon outgrowth and pathfinding. It is anticipated that the proposed research will provide molecular and genetic underpinnings for axon growth cone guidance. An aggressive MDM causes binucleate cells in trophoblast cells but not in blastocysts. Morphological observations were performed on 18-day-old blastocysts and 21-day-old trophoblast tissue from B6C3F1 hybrid mice, which were produced by ICR/Bom and ICR/Jcl mating and fertilization. Morphological changes in trophoblast cells, such as binucleation, were observed, but none were observed in blastocysts. This observation may account for the low rate of pregnancy achieved by the ICR/Jcl combination. We attempted to induce binucleation in trophoblast cells using trichostatin A and caused binucleate cells in trophoblast cells in culture. This induction process was successful. The timing of binucleate cell induction was different depending on the age of the blastocysts, and the percentage of binucleate cells was different among trophoblast cells and blastocysts. The results indicate that age and timing of induction are important factors in binucleation in trophoblast cells. Q: XSD: any element inside another element that is restricted to a list?
